The theoretical foundation of MD

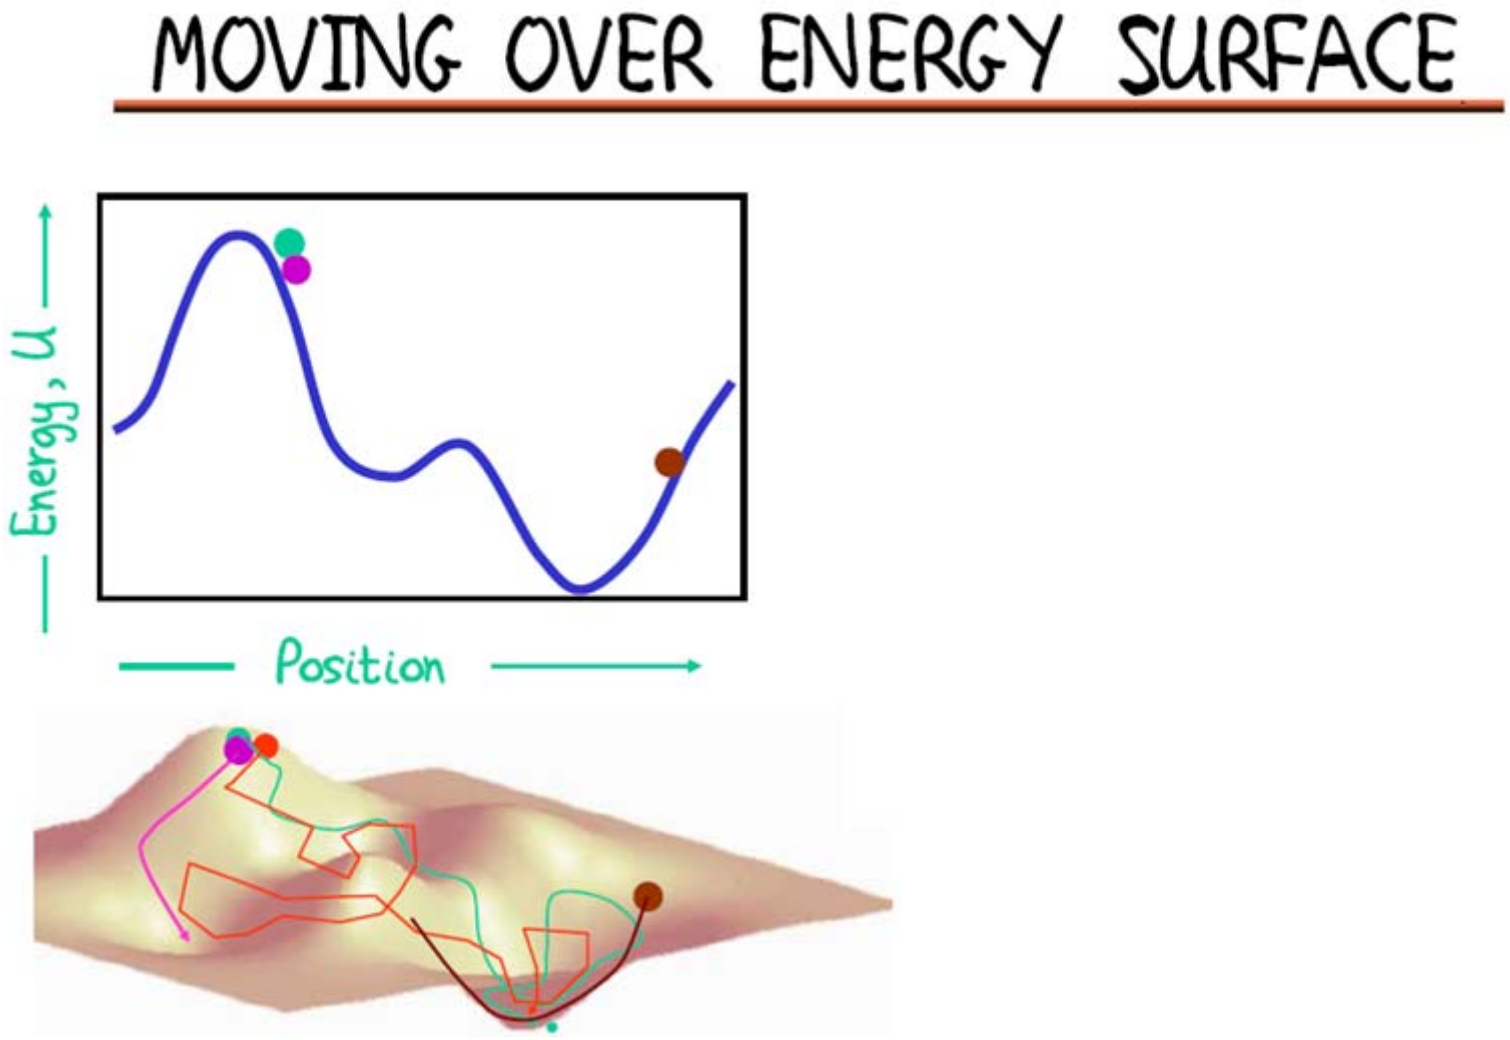
Why MD simulation of a molecular system is possible in theory?

Ergodic theorem (各态历经定理)

A system explores all possible states and can effectively attain thermal equilibrium

$$\langle A \rangle_{ensemble} = \langle A \rangle_{time}$$

Free Energy landscape



The history of MD

Brief history of MD

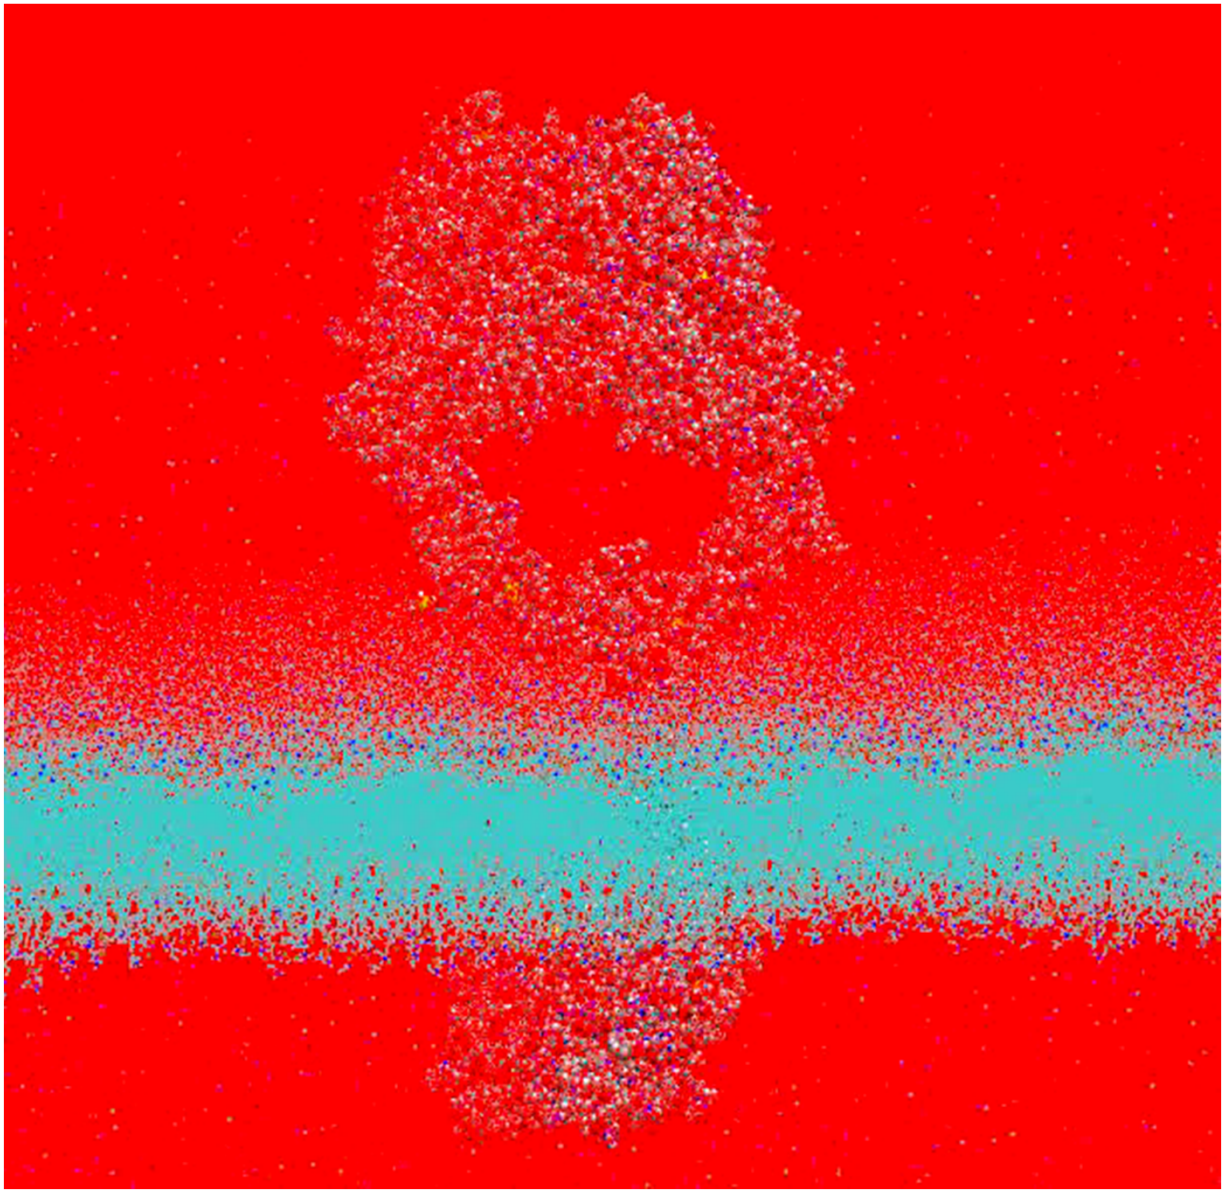
- 1953: Metropolis Monte Carlo (MC) by Metropolis, Rosenbluth, Rosenbluth, Teller & Teller
  - –simulation of a dense liquid of 2D spheres
- 1955: Fermi, Pasta, and Ulam
  - –simulation of anharmonic 1D crystal
- 1956: Alder and Wainwright
  - –molecular dynamics (MD) simulation of hard spheres
- (1958: First X-ray structure of a protein)
- 1960: Vineyard group
  - – Simulation of damaged Cu crystal

Brief history of MD

- 1964: Rahman
  - MD simulation of liquid Ar
- 1969: Barker and Watts
  - Monte Carlo simulation of water
- 1971: Rahman and Stillinger
  - MD simulation of water

Brief history of MD

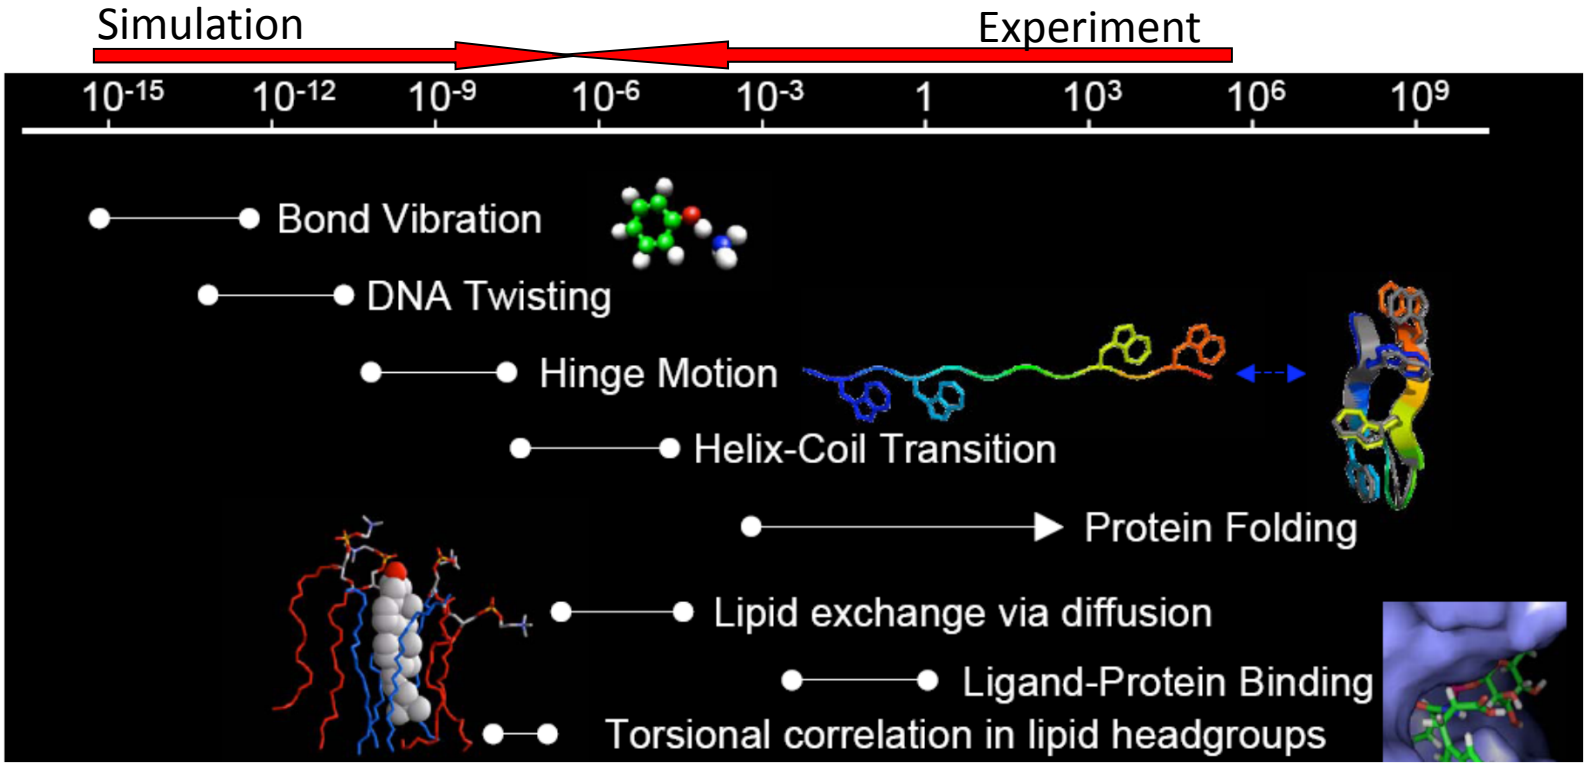
- 1970s: Simulations of small solutes and peptides
- 1977: McCammon, Gelin, Karplus
  - First MD simulation of proteins
- 1980s:
  - Free energy calculations
  - Protein-ligand docking calculations
- 1990s:
  - Continued force field development and sampling techniques
- 1998: Duan and Kollman: 1μs MD simulation of the folding of the Villin headpiece in explicit solvent
- 2009: Anton supercomputer specialized for MD
- 200: Karplus, Warshel, and Levitt--- Nobel Chemistry prize



ANTON

D E Shaw Research

Biomolecular Timescales



Adapted from Suits (IBM), originally from Chan & Dill (1993)

fs – time step during MD

μs - of marginal biological interest (already a billion steps)

ms - this is where things get interesting (a trillion steps)

Understanding trajectories

- Proteins tend to have a small number of important states
- Transitions between states are sudden events
- States often live for tens of microseconds to milliseconds

MOLECULAR STRUCTURE OF NUCLEIC ACIDS

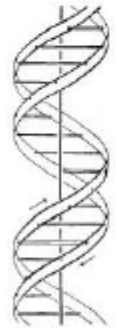
A Structure for Deoxyribose Nucleic A

We wish to suggest a structure for the of deoxyribose nucleic acid (D.N.A.). structure has novel features which are of conside biological interest.

A structure for nucleic acid has already proposed by Pauling and Corey[2]. They kindly their manuscript available to us in advanc publication. Their model consists of three twined chains, with the phosphates near the axis, and the bases on the outside. In our opi this structure is unsatisfactory for two reas (1) We believe that the material which gives X-ray diagrams is the salt, not the free acid. Wit the acidic hydrogen atoms it is not clear what f would hold the structure together, especially s negatively charged phosphates near the axis repel each other. (2) Some of the van der W distances appear to be too small.

Another three-chain structure has also been gested by Fraser (in the press). In his model phosphates are on the outside and the bases on inside, linked together by hydrogen bonds. structure as described is rather ill-defined, and this reason we shall not consi on it.

We wish to put forwa radically different structure the salt of deoxyribose n acid. This structure has helical chains each coiled r the same axis (see diagram). have made the usual chemical assumptions, namely, that each chain consists of phosphate di-ester groups joining β-D-deoxyribofuranose residues with 3',5' linkages. The two chains (but not their bases) are related by a dyad perpendicular to the fibre axis. Both chains follow right-handed helices, but owing to the dyad the sequences of the atoms in the two chains run in opposite directions. Each chain loosely resembles Furberg's[3] model No. 1; that is, the bases are on the inside of the helix and the phosph the outside. The conn of the sugar and the near it is close to P 'standard configuratio sugar being roughly p cular to the attached base

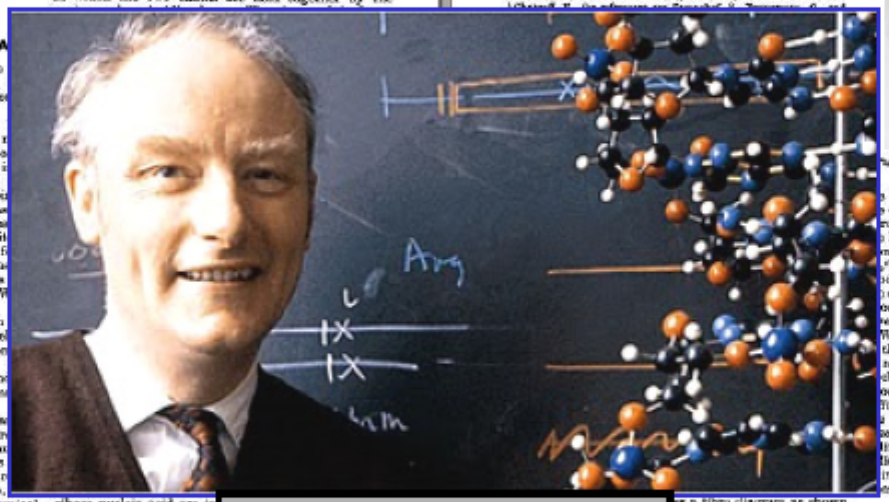


This figure is purely diagrammatic. The two ribbons symbolize the two phosphate–sugar chains, and the horizontal rods the pairs of bases holding the chains together. The vertical line marks the fibre axis

is a residue on each chain every 3·4 A. in the z-direction. We have assumed an angle of 36° between adjacent residues in the same chain, so that the structure repeats after 10 residues on each chain, that is, after 34 A. The distance of a phosphorus atom from the fibre axis is 10 A. As the phosphates are on the outside, cations have easy access to them.

The structure is an open one, and its water content is rather high. At lower water contents we would expect the bases to tilt so that the structure could become more compact.

The novel feature of the structure is the manner in which the two chains are held together by the



1916–2004

ribose nucleic acid are in of our structure. So far compatible with the exp be regarded as improve against more exact resul in the following comman of the details of the resi devised our structure, w entirely on published experimental data and stereochemical arguments.

It has not escaped our notice that the specific pairing we have postulated immediately suggests a possible copying mechanism for the genetic material.

Full details of the structure, including the conditions assumed in building it, together with a set of co-ordinates for the atoms, will be published

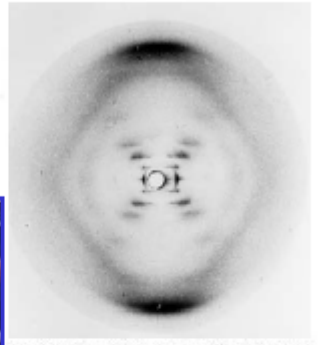

Fig. 1. Fibre diagram of deoxyribose nucleic acid from *B. sub.* Fibre axis vertical

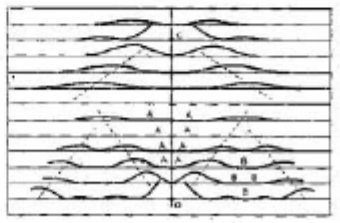
innermost maxima of each Bessel function and origin. The angle this line makes with the equator roughly equal to the angle between an element of helix and the helix axis. If a unit repeats n times ng the helix there will be a meridional reflexion /*n* on the *n*th layer line. The helical configuration duces side-bands on this fundamental frequency, effect being to reproduce the intensity distribution out the origin around the new origin, on the *n*th er line, corresponding to *C* in Fig. 3.

We will now briefly analyse in physical terms some the effects of the shape and size of the repeat unit nucleotide on the diffraction pattern. First, if the cleotide consists of a unit having circular symmetry out an axis parallel to the helix axis, the whole fraction pattern is modified by the form factor of a nucleotide. Second, if the nucleotide consists of series of points on a radius at right angles to the lix axis, the phases of radiation scattered by the lices of different diameter passing through each nt are the same. Summation of the corresponding ssel functions gives reinforcement for the inner-



3. Diffraction pattern of system of radii corresponding to ture of deoxyribose nucleic acid. The crosses of Bessel tions are joined about 0 on the equator and on the first, ird, third and fifth layer lines for half of the nucleotide radii 3 A. diameter and remainder distributed along a radius, the s as a circle radius being proportional to the radius. About h the fourth layer line at 0·17 reflexions are plotted on an outer diameter of 12 A.

The REAL HERO of structural biology.

Why MD simulation

- MD simulations provide a molecular level picture of structure and dynamics of biological systems → property/structure relationships
- Experiments often do not provide the molecular level information available from simulations
- Simulators and experimentalists can have a synergistic relationship, leading to new insights into materials properties

Protein folding
