# A unified fast method for the fractional operators 

Fanhai Zeng<br>Shandong University

Collaborators: Yuxiang Huang, Ling Guo, and Zheng Yang
July 2023

## Outlines

- Background
- Construction of the fast method, applications, and convergence
- Numerical examples

## Background

Develop the fast method to calculate the convolution

$$
\begin{equation*}
k * u(t)=\int_{0}^{t} k(t-s) u(s) \mathrm{d} s \tag{1}
\end{equation*}
$$

The convolution (1) arises in

- the integral models, i.e., the fractional differential equations, describing the anomalous diffusion ${ }^{1}$.
- wave propagation on bounded domains, which requires to impose transparent (nonreflecting) boundary conditions 2345

$$
\hat{u}_{j}(x, t)=-\int_{0}^{t} f_{j}(t-s) \partial_{\nu} \hat{u}_{j}(x, s) \mathrm{d} s, \quad x \in \partial \Omega
$$

1D Schrodinger EQ: 1/2-order Caputo fractional derivative

The fractional operator: choosing $k(t)=k_{\alpha}(t)=\frac{t^{\alpha-1}}{\Gamma(\alpha)}$ yields

$$
\begin{equation*}
k_{\alpha} * u(t)=\int_{0}^{t} \frac{(t-s)^{\alpha-1}}{\Gamma(\alpha)} u(s) \mathrm{d} s . \tag{2}
\end{equation*}
$$

- The Riemann-Liouville (RL) fractional integral of order $\alpha$ for $\alpha>0$;
- The RL fractional derivative of order $-\alpha>0$ for $\alpha<0$ in the sense of Hardamard finite-part integral.

$$
\text { An example: } \quad \begin{align*}
k_{-\alpha} * u(t) & =P . V .\left[\int_{0}^{t} \frac{(t-s)^{-\alpha-1}}{\Gamma(-\alpha)} u(s) \mathrm{d} s\right]  \tag{3}\\
& =\frac{d}{d t}\left[\left(k_{1-\alpha} * u\right)(t)\right], \quad 0<\alpha<1 .
\end{align*}
$$

- Variable-order fractional operators: $\alpha=\alpha(t)$

$$
\begin{equation*}
k_{\alpha(t)} * u(t)=\int_{0}^{t} \frac{(t-s)^{\alpha(t)-1}}{\Gamma(\alpha(t))} u(s) \mathrm{d} s \tag{4}
\end{equation*}
$$

- How about $\alpha=\alpha(s)$ in (4)?
- Interpolation: uniform or nonuniform grid points $\left\{t_{0}, t_{1}, \ldots, t_{M}\right\}$

$$
\begin{equation*}
\left(k_{\alpha} * u\right)\left(t_{n}\right) \approx\left(k_{\alpha} * I_{\tau} u\right)\left(t_{n}\right)=\sum_{k=0}^{n} \omega_{n, k} u\left(t_{k}\right), \quad 1 \leq n \leq M \tag{5}
\end{equation*}
$$

- Convolution quadrature (CQ, fractional linear multistep method): uniform grid points $t_{k}=k \tau, \tau>0$ is a step size

$$
\begin{equation*}
\left(k_{\alpha} * u\right)\left(t_{n}\right) \approx \underbrace{\sum_{k=0}^{n} \omega_{n-k} u\left(t_{k}\right)}_{\text {convolution part }}+\underbrace{\sum_{j=0}^{m} W_{n, j} u\left(t_{j}\right)}_{\text {corrections }}, \quad 1 \leq n \leq M \tag{6}
\end{equation*}
$$

where $\omega_{n}$ are the coefficients of the Taylor expansion of the generating function,

$$
\omega(z)=\sum_{n=0}^{\infty} \omega_{n} z^{n}
$$

which can be derived from the generating function of the linear multistep method.

## Storage and computational cost

Direct calculation of

$$
\begin{equation*}
k_{\alpha} * u\left(t_{n}\right) \approx \sum_{k=0}^{n} w_{n, k} u\left(t_{k}\right), \quad 1 \leq n \leq M \tag{7}
\end{equation*}
$$

needs

1) storage: $O(M) \rightarrow O(1)$ as $\alpha \rightarrow \pm 1$. For example, for linear interpolation and $\alpha \rightarrow-1$, (7) reduces to

$$
\sum_{k=0}^{n} w_{n, k} u\left(t_{k}\right) \rightarrow \frac{u\left(t_{n}\right)-u\left(t_{n-1}\right)}{t_{n}-t_{n-1}}
$$

2) computational cost: $O\left(M^{2}\right) \rightarrow O(M)$ as $\alpha \rightarrow \pm 1$

Fast calculation yields

1) storage: $O(\log (M))$ or $O(Q) ; \quad \log (M) \ll M, Q \ll M$.
2) computational cost: $O(M \log (M))$ or $O(Q M)$.

## Sum-of-exponentials

The basic idea is to seek a suitable sum-of-exponentials to approximate the kernel function $k_{\alpha}(t)=t^{\alpha-1} / \Gamma(\alpha)$, i.e.,

$$
\begin{equation*}
k_{\alpha}(t)=\frac{t^{\alpha-1}}{\Gamma(\alpha)}=\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}+O\left(\varepsilon t^{\alpha-1}\right) \tag{8}
\end{equation*}
$$

where $\varepsilon>0$ is a given precision.

- Global approximation: (8) holds for $\forall t \in[\delta, T], \delta, T>0$.
- Local approximation: (8) holds for $\forall t \in I_{\ell} \subset[\delta, T]$, i.e., $I_{\ell}=\left[B^{\ell-1} \tau, 2 B^{\ell} \tau\right], B>1$ is a positive integer, satisfying

$$
[\delta, T] \subset I_{1} \cup I_{2} \cup I_{3} \cup \cdots \cup I_{L}, \quad L=\left\lceil\log _{B}^{(T / \tau)}\right\rceil=O(\log (T / \tau))
$$

## The method based on the numerical Laplace transform inversion

The Laplace transform of the kernel function $k_{\alpha}(t)=t^{\alpha-1} / \Gamma(\alpha)$ is

$$
K_{\alpha}(\lambda)=\mathcal{L}\left[k_{\alpha}\right](\lambda)=\lambda^{-\alpha}
$$

The inverse Laplace transform yields [Lubich and Schädle, SISC, 2002;
López-Fernández, Lubich, and Schädle, SISC, 2008]

$$
\begin{align*}
k_{\alpha}(t) & =\frac{1}{2 \pi \mathrm{i}} \int_{\mathcal{C}} K_{\alpha}(\lambda) e^{t \lambda} \mathrm{~d} \lambda=\frac{1}{2 \pi \mathrm{i}} \int_{\mathcal{C}} \lambda^{-\alpha} e^{t \lambda} \mathrm{~d} \lambda \\
& =\frac{1}{2 \pi \mathrm{i}} \int_{-\pi}^{\pi}(z(\theta))^{-\alpha} z^{\prime}(\theta) e^{t z(\theta)} \mathrm{d} \theta \quad(\lambda=z(\theta))  \tag{9}\\
& \approx \sum_{j=-N+1}^{N} w_{j}^{(\ell)} e^{\lambda_{j}^{(\ell)} t} \quad t \in I_{\ell}=\left[B^{\ell-1} \tau, 2 B^{\ell} \tau\right]
\end{align*}
$$

where $w_{j}^{(\ell)}=\frac{1}{2 \pi \mathrm{i}}\left(\lambda_{j}^{(\ell)}\right)^{-\alpha} \partial_{\theta} z\left(\theta_{j}, \mu_{\ell}\right), \lambda_{j}^{(\ell)}=z\left(\theta_{j}, \mu_{\ell}\right), \theta_{j}=\frac{(2 j-1) \pi}{2 N}$.

- The optimal Talbot contour with $z\left(\theta, \mu_{\ell}\right)$ given by [Weideman, SINUM, 2006]

$$
\begin{equation*}
z\left(\theta, \mu_{\ell}\right)=\mu_{\ell}(-0.4814+0.6443(\theta \cot (\theta)+\mathrm{i} 0.5653 \theta)) \tag{10}
\end{equation*}
$$

where $\mu_{\ell}=N / T_{\ell}, T_{\ell}=2 B^{\ell} \tau, B>1$ is a positive integer.

- The hyperbolic contour with $z\left(\theta, \mu_{\ell}\right)$ given by [Lopez-Fernandez, Lubich, et al., Numer. Math., 2005]

$$
\begin{equation*}
z\left(\theta, \mu_{\ell}\right)=\mu_{\ell}(1-\sin (\psi+\mathrm{i} \theta))+\sigma \tag{11}
\end{equation*}
$$

In numerical simulations, we can select $\sigma=0, \psi=0.4 \pi, \mu_{\ell}=N / T_{\ell}$, $T_{\ell}=B^{\ell} \tau, N=\left\lceil-\log \left(\tau^{1-\alpha} \epsilon\right)\right\rceil, \epsilon$ is a given precision.

Find a rational approximation $r(\lambda)$ to the Laplace transform of

$$
k_{\alpha}(t+\delta)=(t+\delta)^{\alpha-1} / \Gamma(\alpha), \delta \geq 0
$$

which takes the following form [Baffet and Hesthaven, SINUM, 2017]

$$
\begin{equation*}
r(\lambda)=\sum_{j=1}^{Q} \frac{c_{j}}{\lambda-\lambda_{j}} \tag{12}
\end{equation*}
$$

Applying the inverse Laplace transform yields

$$
\begin{equation*}
k_{\alpha}(t+\delta) \approx \frac{1}{2 \pi \mathrm{i}} \int_{\mathcal{C}} r(\lambda) e^{t \lambda} \mathrm{~d} \lambda=\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t} \tag{13}
\end{equation*}
$$

The method based on the Jacobi-Gauss quadrature
$k_{\alpha}(t)=\frac{t^{\alpha-1}}{\Gamma(\alpha)}$ can be expressed as

$$
\begin{align*}
k_{\alpha}(t) & =\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda \quad(\alpha<1) \\
& =\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{A} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda+O\left(\varepsilon t^{\alpha-1}\right) \tag{14}
\end{align*}
$$

Taking $A=2^{m_{2}}$ yields

$$
\begin{align*}
\int_{0}^{A} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda & =\underbrace{\int_{0}^{2^{-m_{1}}} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda}_{\text {Jacobi-Gauss }}+\sum_{k=-m_{1}}^{m_{2}-1} \underbrace{\int_{2^{k}}^{2^{k+1}} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda}_{\text {Legendre-Gauss }}  \tag{15}\\
& \approx \sum_{j=1}^{N_{o}} w_{j}^{(o)} e^{-\lambda_{j}^{(o)} t}+\sum_{k=-m_{1}}^{m_{2}-1} \sum_{j=1}^{N_{k}} w_{j}^{(k)}\left(\lambda_{j}^{(k)}\right)^{-\alpha} e^{-\lambda_{j}^{(k)} t}
\end{align*}
$$

Jacobi-Gauss quadrature [Jiang, Zhang, Zhang, and Zhang, Commun.
Comput. Phys., 2017]

$$
\begin{aligned}
k_{\alpha}(t) & \approx \frac{\sin (\alpha \pi)}{\pi} \int_{0}^{A} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda \\
& \approx \frac{\sin (\alpha \pi)}{\pi}\left(\sum_{j=1}^{N_{o}} w_{j}^{(o)} e^{-\lambda_{j}^{(o)} t}+\sum_{k=-m_{1}}^{m_{2}-1} \sum_{j=1}^{N_{k}} w_{j}^{(k)}\left(\lambda_{j}^{(k)}\right)^{-\alpha} e^{-\lambda_{j}^{(k)} t}\right) \\
& =\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}
\end{aligned}
$$

Legendre-Gauss quadrature [Jing-Rebecca Li, SISC, 2010]

$$
\begin{align*}
k_{\alpha}(t) & \approx \underbrace{\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\sigma} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda}_{O(\varepsilon)}+\frac{\sin (\alpha \pi)}{\pi} \int_{\sigma}^{A} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda \\
& \approx \frac{\sin (\alpha \pi)}{\pi}\left(\sum_{k=-m_{1}}^{m_{2}-1} \sum_{j=1}^{N_{k}} w_{j}^{(k)}\left(\lambda_{j}^{(k)}\right)^{-\alpha} e^{-\lambda_{j}^{(k)} t}\right)  \tag{17}\\
& =\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}
\end{align*}
$$

Rewrite

$$
k_{\alpha}(t)=\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda
$$

as

$$
\begin{align*}
k_{\alpha}(t) & =\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\infty} \underbrace{\lambda^{-\alpha} e^{-T_{\ell} \lambda}}_{\text {weight }} e^{-\left(t-T_{\ell}\right) \lambda} \mathrm{d} \lambda \\
& =\frac{\sin (\alpha \pi)}{\pi} \sum_{j=1}^{N} w_{j}^{(\ell)} e^{-\left(t-T_{\ell}\right) \lambda_{j}^{(\ell)}}+O(\varepsilon), \quad t-T_{\ell} \in I_{\ell}  \tag{18}\\
& =\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}+O(\varepsilon)
\end{align*}
$$

See [Zeng, Turner, Burrage, JSC, 2018].

## The method based on the trapezoidal rule on the real line

Let $\lambda=e^{x}$. Then

$$
\begin{equation*}
k_{\alpha}(t)=\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda=\int_{-\infty}^{\infty} \underbrace{\frac{\sin (\alpha \pi)}{\pi} e^{-t e^{x}+(1-\alpha) x}}_{\phi(x, t)} \mathrm{d} x, \tag{19}
\end{equation*}
$$

where $|\phi(x, t)| \rightarrow 0$ as $|x| \rightarrow \infty$ for $t>0$. The trapezoidal rule for approximating (19) is [Trefethen, Weideman, SIAM Rev., 2014; McLean, Contemporary Computational Mathematics, 2018]

$$
\begin{align*}
k_{\alpha}(t) & =h \sum_{j=-\infty}^{\infty} \phi(j h, t)+O\left(e^{-1 / h}\right) \\
& =\underbrace{h \sum_{j=-\infty}^{-N_{1}-1} \phi(j h, t)}_{O(\varepsilon)}+h \sum_{j=-N_{1}}^{N_{2}} \phi(j h, t)+\underbrace{h \sum_{j=N_{2}+1}^{\infty} \phi(j h, t)}_{O(\varepsilon)}+O\left(e^{-1 / h}\right) \\
& =\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}+O\left(e^{-1 / h}\right)+O(\varepsilon) \tag{20}
\end{align*}
$$

Table: Comparison of different methods for approximating $k_{\alpha}(t)=t^{\alpha-1} / \Gamma(\alpha)$.

| Kernel <br> approximation <br> method | Range <br> of $\alpha$ | Are $\lambda_{j}$ <br> dependent <br> on $\alpha ?$ | Extension to <br> variable-order <br> $\alpha=\alpha(t) ?$ | Global/Local <br> approximation |
| :---: | :---: | :---: | :---: | :---: |
| Contour <br> quadrature (9) | $\alpha \in \mathbb{R}$ | No | Yes | Local, $t \in I_{\ell}$ |
| Multi-pole <br> method (13) | $\alpha<1$ | Yes | No | Global, $t \in[\delta, T]$ |
| Jacobi-Gauss <br> quadrature (16) | $\alpha<1$ | Yes | No | Global |
| Legendre-Gauss <br> quadrature (17) | $\alpha<1$ | No | Yes | Global |
| Laguerre-Gauss <br> quadrature (18) | $\alpha<1$ | Yes | No | Local |
| Trapezoidal <br> rule (20) | $\alpha<1$ | No | Yes | Global |

Compare the different kernel approximation methods.
Define the relative error

$$
e(t)=\left|\frac{k_{\alpha}(t)-\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}}{k_{\alpha}(t)}\right|
$$

Figure: Comparison of different kernel approximation methods, $\delta=0.1$, $T=1000, \alpha=-0.4$, and $B=5$.

Figure: Comparison of different kernel approximation methods, $\delta=0.1$, $T=1000, \alpha=0.4$, and $B=5$.

(a) $Q=17 \times 6=102$.

(c) $Q=54 \times 6=324$.

(b) $Q=26 \times 6=156$.

(d) $Q=76 \times 6=456$.

Figure: Comparison of different kernel approximation methods, $\delta=0.1$, $T=1000, \alpha=0.95$, and $B=5$.

## An improved kernel approximation method

We already have

$$
\begin{equation*}
k_{\alpha}(t)=\frac{\sin (\alpha \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha} e^{-t \lambda} \mathrm{~d} \lambda \approx \sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}(\alpha) t}, \quad \alpha<1 \tag{21}
\end{equation*}
$$

Hence, $k_{\alpha}(t)$ can be approximated by

$$
\begin{align*}
k_{\alpha}(t) & =\frac{t}{\alpha-1} k_{\alpha-1}(t) \\
& \approx \frac{t}{\alpha-1} \sum_{j=1}^{Q} w_{j}(\alpha-1) e^{\lambda_{j}(\alpha-1) t} \quad(\alpha<2)  \tag{22}\\
& =t \sum_{j=1}^{Q} \widehat{w}_{j} e^{\widehat{\lambda}_{j} t}
\end{align*}
$$

where $\widehat{w}_{j}=\frac{w_{j}(\alpha-1)}{\alpha-1}, \widehat{\lambda}_{j}=\lambda_{j}(\alpha-1)$.

$$
k_{\alpha}(t)=\frac{t^{2}}{(\alpha-1)(\alpha-2)} k_{\alpha-2}(t), \quad \alpha \in(2,3)
$$

(a) The hyperbolic quadrature.

(b) The improved method.

Figure: Comparison between the hyperbolic quadrature (9) based on the contour quadrature (11) and the improved method (22), $Q=256$.

## Variable-order fractional case

Table: Comparison of different methods for approximating $k_{\alpha}(t)=t^{\alpha-1} / \Gamma(\alpha)$.

| Kernel <br> approximation <br> method | Range <br> of $\alpha$ | Are $\lambda_{j}$ <br> dependent <br> on $\alpha ?$ | Extension to <br> variable-order <br> $\alpha=\alpha(t) ?$ | Global/Local <br> approximation |
| :---: | :---: | :---: | :---: | :---: |
| Contour <br> quadrature (9) | $\alpha \in \mathbb{R}$ | No | Yes | Local |
| Multi-pole <br> method (13) | $\alpha<1$ | Yes | No | Global |
| Jacobi-Gauss <br> quadrature (16) | $\alpha<1$ | Yes | No | Global |
| Legendre-Gauss <br> quadrature (17) | $\alpha<1$ | No | Yes | Global |
| Laguerre-Gauss <br> quadrature (18) | $\alpha<1$ | Yes | No | Local |
| Trapezoidal <br> rule (20) | $\alpha<1$ | No | Yes | Global |

## Variable-order fractional case: $\alpha=\alpha(t)$

Contour quadrature: From (9), we can obtain

$$
\begin{equation*}
k_{\alpha(t)}(t)=\frac{t^{\alpha(t)-1}}{\Gamma(\alpha(t))}=\frac{1}{2 \pi \mathrm{i}} \int_{C} \lambda^{-\alpha(t)} e^{t \lambda} \mathrm{~d} \lambda \tag{23}
\end{equation*}
$$

## Legendre-Gauss quadrature:

$$
\begin{align*}
k_{\alpha(t)}(t) & =\frac{\sin (\alpha(t) \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha(t)} e^{-t \lambda} \mathrm{~d} \lambda \\
& =\frac{\sin (\alpha(t) \pi)}{\pi} \int_{\sigma}^{A} \lambda^{-\alpha(t)} e^{-t \lambda} \mathrm{~d} \lambda+O(\varepsilon)  \tag{24}\\
& =\frac{\sin (\alpha(t) \pi)}{\pi} \sum_{j=1}^{K} \int_{\sigma_{j-1}}^{\sigma_{j}} \lambda^{-\alpha(t)} e^{-t \lambda} \mathrm{~d} \lambda+O(\varepsilon)
\end{align*}
$$

Trapezoidal rule: $\lambda=e^{x}$

$$
\begin{align*}
k_{\alpha(t)}(t) & =\frac{\sin (\alpha(t) \pi)}{\pi} \int_{0}^{\infty} \lambda^{-\alpha(t)} e^{-t \lambda} \mathrm{~d} \lambda \\
& =\frac{\sin (\alpha(t) \pi)}{\pi} \int_{-\infty}^{\infty} e^{(1-\alpha(t)) x} e^{-t e^{x}} \mathrm{~d} x \tag{25}
\end{align*}
$$

Figure: Comparison of different kernel approximations for variable-order fractional orders, $\tau=1, T=1000$, and $Q=N \times L=64 \times 4=256$. The trapezoidal rule shows better accuracy than the other two methods for negative $\alpha(t)$, but displays the worst accuracy when $\alpha(t)>0$.

(a) $\alpha(t)=\left(\frac{1}{20}+\frac{9}{10} \sin ^{2}(10 t)\right)$.

(b) $\alpha(t)=-\left(\frac{1}{20}+\frac{9}{10} \sin ^{2}(10 t)\right)$.

Figure: The accuracy of the Legendre-Gauss quadrature for the method (17) for the variable order fractional case, $\tau=1, T=1000, m_{2}=6$, $N=16$, and $Q=N \times m$.

## The unified fast time-stepping method

1. Fast method for RL fractional integral $\left(k_{\alpha} * u\right)(t)$ is

$$
\mathcal{F}(\alpha), \quad \alpha>0 .
$$

Fast method for RL fractional derivative ${ }_{R L} D_{0, t}^{\alpha} u(t)=P . V .\left(\left(k_{-\alpha} * u\right)(t)\right)$ is

$$
\mathcal{F}(-\alpha), \quad \alpha>0 .
$$

2. Fast method for the Caputo fractional derivative

$$
{ }_{C} D_{0, t}^{\alpha} u(t)=\left(k_{m-\alpha} * u^{(m)}\right)(t)=P . V \cdot\left(k_{-\alpha} *(u-\phi)(t)\right), \quad m-1<\alpha<m
$$

reads as

$$
\mathcal{F}(-\alpha)+\mathcal{B}(\alpha)
$$

For a smooth $u(t), \phi(t)=\sum_{j=0}^{m-1} \frac{u^{(j)}(0)}{\Gamma(j+1)} t^{j}$, so that

$$
\mathcal{B}(\alpha)=-\sum_{j=0}^{m-1} \frac{t^{j-\alpha}}{\Gamma(j+1-\alpha)} u^{(j)}(0) .
$$

The linear interpolation operator $\Pi^{1}: C[0, T] \rightarrow C[0, T]$ reads as

$$
\begin{equation*}
\left.\Pi^{1} u(t)\right|_{t \in\left[t_{j-1}, t_{j}\right]}=\frac{t-t_{j}}{t_{j-1}-t_{j}} u\left(t_{j-1}\right)+\frac{t-t_{j-1}}{t_{j}-t_{j-1}} u\left(t_{j}\right) \tag{26}
\end{equation*}
$$

Then the convolution integral $\left(k_{\alpha} * u\right)(t)$ can be approximated by

$$
\begin{equation*}
D^{-\alpha, n} u=\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)=\sum_{j=1}^{n}\left(A_{n, j}^{(\alpha)} u^{j-1}+B_{n, j}^{(\alpha)} u^{j}\right) \tag{27}
\end{equation*}
$$

where $u^{j}=u\left(t_{j}\right)$ and

$$
\begin{align*}
A_{n, j}^{(\alpha)} & =\int_{t_{j-1}}^{t_{j}} k_{\alpha}\left(t_{n}-s\right) \frac{s-t_{j}}{t_{j-1}-t_{j}} \mathrm{~d} s  \tag{28}\\
B_{n, j}^{(\alpha)} & =\int_{t_{j-1}}^{t_{j}} k_{\alpha}\left(t_{n}-s\right) \frac{s-t_{j-1}}{t_{j}-t_{j-1}} \mathrm{~d} s
\end{align*}
$$

- $\alpha>0$ : (27) is the fractional trapezoidal rule.
- $\alpha<0$ : (27) is the popularly used L1 method for discretizing the RL fractional derivative.

The aim of this section is to design fast algorithms to calculate

$$
\begin{equation*}
\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)=\int_{t_{0}}^{t_{n}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s=\sum_{j=1}^{n}\left(A_{n, j}^{(\alpha)} u_{j-1}+B_{n, j}^{(\alpha)} u_{j}\right) . \tag{29}
\end{equation*}
$$

Divide $\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)$ into two parts as

$$
\begin{equation*}
\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)=\underbrace{\int_{t_{n-1}}^{t_{n}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {Local part : } L^{\alpha, n} u}+\underbrace{\int_{0}^{t_{n-1}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {History part : } H^{\alpha, n} u} \tag{30}
\end{equation*}
$$

where the local part $L^{\alpha, n} u$ and the history part $H^{\alpha, n} u$ can also be expressed as

$$
\begin{align*}
L^{\alpha, n} u & =A_{n, n}^{(\alpha)} u^{n-1}+B_{n, n}^{(\alpha)} u^{n}  \tag{31}\\
H^{\alpha, n} u & =\sum_{j=1}^{n-1}\left(A_{n, j}^{(\alpha)} u^{j-1}+B_{n, j}^{(\alpha)} u^{j}\right) \tag{32}
\end{align*}
$$

Develop the fast memory-saving method to calculate the history part $H^{\alpha, n} u$.

The history part $H^{\alpha, n} u$ can be approximated via

$$
\begin{align*}
H^{\alpha, n} u & =\underbrace{\sum_{j=1}^{n-1}\left(A_{n, j}^{(\alpha)} u^{j-1}+B_{n, j}^{(\alpha)} u^{j}\right)}_{\text {Direct calculation }}=\int_{0}^{t_{n-1}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s \\
& \approx \underbrace{\int_{0}^{t_{n-1}} \sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}\left(t_{n}-s\right)} \Pi^{1} u(s) \mathrm{d} s}_{Y_{j}\left(t_{n-1}\right)} \\
& =\underbrace{\sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}\left(t_{n}-t_{n-1}\right)} \underbrace{t_{0}^{t_{n-1}} e^{\lambda_{j}\left(t_{n-1}-s\right)} \Pi^{1} u(s) \mathrm{d} s}_{{ }_{F} H^{\alpha, n} u}}_{\text {Fast calculation }}  \tag{33}\\
& =\sum_{j=1}^{\sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}\left(t_{n}-t_{n-1}\right)} Y_{j}\left(t_{n-1}\right)}
\end{align*}
$$

where $Y_{j}(t)$ satisfies the following ODE

$$
\begin{equation*}
Y_{j}^{\prime}(t)=\lambda_{j} Y_{j}(t)+\Pi^{1} u(t), \quad Y_{j}(0)=0 \tag{34}
\end{equation*}
$$

The above linear ODE has the analytical solution

$$
Y_{j}(t)=e^{\lambda_{j} t} Y_{j}(0)+\int_{0}^{t} e^{\lambda_{j}(t-s)} \Pi^{1} u(s) \mathrm{d} s,
$$

which can be exactly solved by the following recursive relation

$$
\begin{align*}
Y_{j}\left(t_{m}\right) & =e^{\lambda_{j}\left(t_{m}-t_{m-1}\right)} Y_{j}\left(t_{m-1}\right)+\int_{t_{m-1}}^{t_{m}} e^{\lambda_{j}\left(t_{m}-t\right)} \Pi^{1} u(t) \mathrm{d} t  \tag{35}\\
& =\Lambda_{1} Y_{j}\left(t_{m-1}\right)+\Lambda_{2} u^{m-1}+\Lambda_{3} u^{m}
\end{align*}
$$

at $t=t_{m}$, where $Y_{j}(0)=0$ and

$$
\left\{\begin{array}{l}
\Lambda_{1}=e^{\lambda_{j}\left(t_{m}-t_{m-1}\right)}  \tag{36}\\
\Lambda_{2}=\frac{1}{\lambda_{j}}\left(e^{z}-1-\frac{e^{z}-z-1}{z}\right), \quad z=\lambda_{j}\left(t_{m}-t_{m-1}\right) \\
\Lambda_{3}=\frac{1}{\lambda_{j}} \frac{e^{z}-z-1}{z}, \quad z=\lambda_{j}\left(t_{m}-t_{m-1}\right)
\end{array}\right.
$$

Algorithm 1: Fast calculation of the fractional operator $k_{\alpha} * u(t)$ based on the kernel approximation

$$
\begin{equation*}
k_{\alpha}(t) \approx \frac{t^{\alpha-1}}{\Gamma(\alpha)}=\sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}(\alpha) t}, \quad t \in[\delta, T] \tag{37}
\end{equation*}
$$

Step 1. Divide $\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)$ into two parts as

$$
\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)=\underbrace{\int_{t_{n-1}}^{t_{n}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {Local part : } L^{\alpha, n} u}+\underbrace{\int_{0}^{t_{n-1}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {History part : } H^{\alpha, n} u}
$$

Step 2. Calculate the local part $L^{\alpha, n} u$ directly by (31).
Step 3. Approximate the history part $H^{\alpha, n} u$ by

$$
\begin{equation*}
{ }_{F} H^{\alpha, n} u=\sum_{j=1}^{Q} w_{j}(\alpha) e^{\lambda_{j}(\alpha)\left(t_{n}-t_{n-1}\right)} Y_{j}\left(t_{n-1}\right), \quad n \geq 2 \tag{38}
\end{equation*}
$$

where ${ }_{F} H^{\alpha, n} u=0$ for $n \leq 1, Y_{j}\left(t_{n-1}\right)$ satisfies (35).
Step 4. Output ${ }_{F} D^{-\alpha, n} u=L^{\alpha, n} u+{ }_{F} H^{\alpha, n} u$.

Algorithm 2: Fast calculation of the fractional operator $k_{\alpha} * u(t)$ based on the improved kernel approximation

$$
\begin{equation*}
k_{\alpha}(t)=\frac{t^{\alpha-1}}{\Gamma(\alpha)}=\frac{t}{\alpha-1} k_{\alpha-1}(t) \approx t \sum_{j=1}^{Q} \widehat{w}_{j} e^{\widehat{\lambda}_{j} t}, \quad t \in[\delta, T] \tag{39}
\end{equation*}
$$

Step 1. Divide $\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)$ into two parts as

$$
\left(k_{\alpha} * \Pi^{1} u\right)\left(t_{n}\right)=\underbrace{\int_{t_{n-1}}^{t_{n}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {Local part : } L^{\alpha, n} u}+\underbrace{\int_{0}^{t_{n-1}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s}_{\text {History part : } H^{\alpha, n} u}
$$

Step 2. Calculate the local part $L^{\alpha, n} u$ directly.
Step 3. Approximate the history part $H^{\alpha, n} u$ by

$$
\begin{equation*}
{ }_{F} H^{\alpha, n} u=\sum_{j=1}^{Q} \widehat{w}_{j}(\alpha) e^{\widehat{\lambda}_{j}\left(t_{n}-t_{n-1}\right)}\left(\left(t_{n} Y_{j}\left(t_{n-1}\right)-Z_{j}\left(t_{n-1}\right)\right), \quad n \geq 2\right. \tag{40}
\end{equation*}
$$

where ${ }_{F} H^{\alpha, n} u=0$ for $n \leq 1, Y_{j}\left(t_{n-1}\right)$ satisfies (35).
Step 4. Output ${ }_{F} D^{-\alpha, n} u=L^{\alpha, n} u+{ }_{F} H^{\alpha, n} u$.

$$
\begin{align*}
H^{\alpha, n} u & =\sum_{j=1}^{n-1}\left(A_{n, j}^{(\alpha)} u^{j-1}+B_{n, j}^{(\alpha)} u^{j}\right)=\int_{0}^{t_{n-1}} k_{\alpha}\left(t_{n}-s\right) \Pi^{1} u(s) \mathrm{d} s \\
& \approx \sum_{j=1}^{Q} \widehat{w}_{j}(\alpha) \int_{0}^{t_{n-1}}\left(t_{n}-s\right) e^{\widehat{\lambda}_{j}\left(t_{n}-s\right)} \Pi^{1} u(s) \mathrm{d} s  \tag{41}\\
& =\sum_{j=1}^{Q} \widehat{w}_{j}(\alpha) e^{\widehat{\lambda}_{j}\left(t_{n}-t_{n-1}\right)}\left(t_{n} Y_{j}\left(t_{n-1}\right)-Z_{j}\left(t_{n-1}\right)\right) \\
& =:{ }_{F} H^{\alpha, n} u
\end{align*}
$$

where

$$
\begin{align*}
& Y_{j}\left(t_{n-1}\right)=\int_{0}^{t_{n-1}} e^{\widehat{\lambda}_{j}\left(t_{n-1}-s\right)} \Pi^{1} u(s) \mathrm{d} s  \tag{42}\\
& Z_{j}\left(t_{n-1}\right)=\int_{0}^{t_{n-1}} e^{\widehat{\lambda}_{j}\left(t_{n-1}-s\right)} s \Pi^{1} u(s) \mathrm{d} s
\end{align*}
$$

## Application to FODEs

Consider the following fractional ODE (FODE)

$$
\left\{\begin{array}{l}
{ }_{C} D_{0, t}^{\alpha(t)} u(t)=-u(t)+f(u, t), \quad 0<\alpha(t) \leq 1, \quad t \in(0, T]  \tag{43}\\
u(0)=u_{0}
\end{array}\right.
$$

where

$$
{ }_{C} D_{0, t}^{\alpha(t)} u(t)=P . V .\left(k_{-\alpha(t)} * u(t)\right)-\frac{t^{-\alpha(t)}}{\Gamma(1-\alpha(t))} u(0)
$$

The fast method for (43) reads: Find ${ }_{F} U^{n}$ for $n \geq 1$ such that

$$
\begin{equation*}
{ }_{F} D^{\alpha_{n}, n}{ }_{F} U-\frac{t_{n}^{-\alpha_{n}}}{\Gamma\left(1-\alpha_{n}\right)}{ }_{F} U^{0}=-{ }_{F} U^{n}+f\left({ }_{F} U^{n}, t_{n}\right), \quad{ }_{F} U^{0}=u_{0} . \tag{44}
\end{equation*}
$$

The direct method for (43) reads: Find $U^{n}$ for $n \geq 1$ such that

$$
\begin{equation*}
D^{\alpha_{n}, n} U-\frac{t_{n}^{-\alpha_{n}}}{\Gamma\left(1-\alpha_{n}\right)} U^{0}=-U^{n}+f\left(U^{n}, t_{n}\right), \quad U^{0}=u_{0} \tag{45}
\end{equation*}
$$

Error of the direct method (uniform time mesh $t_{j}=j \tau$ )

$$
R^{n}={ }_{C} D_{0, t}^{\alpha} u\left(t_{n}\right)-{ }_{c} D_{0, t}^{\alpha} \Pi^{1} u\left(t_{n}\right)=O\left(\tau^{2-\alpha}\right)
$$

## Theorem (Huang, Zeng, Guo, 2022)

Assume that

$$
\begin{equation*}
k_{-\alpha}(t)=\frac{t^{-\alpha-1}}{\Gamma(-\alpha)}=\sum_{j=1}^{Q} w_{j} e^{\lambda_{j} t}+O\left(\varepsilon t^{-\alpha-1}\right), \quad t \in[\delta, T] . \tag{46}
\end{equation*}
$$

Let $U^{n}$ and ${ }_{F} U^{n}$ be the solutions of the direct method and fast method, respectively. If $\tau$ is sufficiently small and $\varepsilon / \tau^{\alpha} \lesssim 1$, then

$$
\begin{equation*}
\left|U^{n}-{ }_{F} U^{n}\right| \lesssim \varepsilon n^{\alpha}, \quad 1 \leq n \leq M \tag{47}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
\left|{ }_{F} U^{n}-u\left(t_{n}\right)\right| \leq \underbrace{\left|U^{n}-{ }_{F} U^{n}\right|}_{\lesssim \varepsilon n^{\alpha}}+\underbrace{\left|U^{n}-u\left(t_{n}\right)\right|}_{\text {Error of the direct method } \leq\left|R^{n}\right|} \tag{48}
\end{equation*}
$$

## Time-fractional PDEs

Semi-linear time-fractional subdiffusion equation

$$
\left\{\begin{array}{l}
{ }_{C} D_{0, t}^{\alpha} u(x, t)=\partial_{x x} u(x, t)+f(u), \quad(x, t) \in \Omega \times(0, T]  \tag{49}\\
u(x, 0)=u_{0}(x), \quad x \in \bar{\Omega} \\
u(x, t)=0, \quad(x, t) \in \partial \Omega \times[0, T]
\end{array}\right.
$$

Fast FDM for (49) is given by: For $1 \leq n \leq n_{T}$, find ${ }_{F} U_{j}^{n}$ such that

$$
\left\{\begin{array}{l}
{ }_{F} D^{\alpha_{n}, n}{ }_{F} U_{j}^{n}=\delta_{x F}^{2} U_{j}^{n}+f\left({ }_{F} U_{j}^{n}\right), \quad 1 \leq j \leq M-1  \tag{50}\\
{ }_{F} U_{0}^{n}={ }_{F} U_{M}^{n}=0, \quad{ }_{F} U_{j}^{0}=u_{0}\left(x_{j}\right), \quad 0 \leq j \leq M
\end{array}\right.
$$

Direct FDM for (49) is given by: For $1 \leq n \leq n_{T}$, find $U_{j}^{n}$ such that

$$
\left\{\begin{array}{l}
D^{\alpha_{n}, n} U_{j}^{n}=\delta_{x}^{2} U_{j}^{n}+f\left(U_{j}^{n}\right), \quad 1 \leq j \leq M-1  \tag{51}\\
U_{0}^{n}=U_{M}^{n}=0, \quad U_{j}^{0}=u_{0}\left(x_{j}\right), \quad 0 \leq j \leq M
\end{array}\right.
$$

## Theorem

Let $u$ and $U_{j}^{n}$ be the solutions of (49) and (51), respectively, $u(\cdot, t) \in C^{4}(\Omega)$, and $f(z)$ satisfies the local Lipschitz condition. If $\tau$ is sufficiently small, then

$$
\left\|u\left(\cdot, t_{n}\right)-U^{n}\right\|_{L^{p}} \lesssim \tau t_{n}^{\alpha-1}+h^{2} t_{n}^{\alpha}, \quad 1 \leq n \leq M
$$

where $p=2, \infty$.
See [Dongfang Li et al., JSC, 2022; Natalia Kopteva and Xiangyun Meng, SINUM, 2020].

## Theorem (Huang, Zeng, Guo, 2022)

Let $U_{j}^{n}$ and ${ }_{F} U_{j}^{n}$ be the solutions of (51) and (50), respectively, $f(z)$ satisfies the local Lipschitz condition. If $\tau$ is sufficiently small and $\varepsilon / \tau^{\alpha} \lesssim 1$, then

$$
\left\|_{F} U^{n}-U^{n}\right\|_{L^{p}} \lesssim \varepsilon n^{\alpha}, \quad 1 \leq n \leq M
$$

where $p=2, \infty$.
Furthermore,

$$
\left\|_{F} U^{n}-u\left(\cdot, t_{n}\right)\right\|_{L^{p}} \lesssim\left(\tau t_{n}^{\alpha-1}+h^{2} t_{n}^{\alpha}\right)+\varepsilon n^{\alpha}, \quad 1 \leq n \leq M
$$

where $p=2, \infty$.

Nonuniform grids

$$
t_{j}=T(j / M)^{r} \quad r=1 \text { reduces to the uniform grid. }
$$

## Theorem (Yang, Zeng, 2022)

Let $U_{j}^{n}$ and ${ }_{F} U_{j}^{n}$ be the solutions of (51) and (50), respectively, $f(z)$ satisfies the local Lipschitz condition. If $\varepsilon M^{\alpha} \lesssim 1$, then

$$
\left\|_{F} U^{n}-U^{n}\right\|_{L^{p}} \lesssim \varepsilon M^{\alpha} t_{n}^{\alpha / r} \lesssim \varepsilon n^{\alpha}, \quad 1 \leq n \leq M
$$

where $p=2, \infty$.
Furthermore,

$$
\left\|_{F} U^{n}-u\left(\cdot, t_{n}\right)\right\|_{L^{p}} \lesssim\left(\text { temporal error }+h^{2} t_{n}^{\alpha}\right)+\varepsilon n^{\alpha}, \quad 1 \leq n \leq M
$$

## Numerical results

Consider the following fractional ODE

$$
\begin{equation*}
{ }_{C} D_{0, t}^{\alpha(t)} u(t)=-u(t)+f(u, t), \quad u(0)=u_{0}, \quad t \in(0, T], \tag{52}
\end{equation*}
$$

where $0<\alpha(t) \leq 1$.
Choose the nonlinear term $f=u\left(1-u^{2}\right)$ and the initial value $u_{0}=1$.
Compute the reference solutions $U_{r e f}^{n}$ with a smaller step size $\tau=10^{-3}$.

(a) Numerical solutions.

(c) Difference $\frac{\left|U^{n}-{ }_{F} U^{n}\right|}{\left|U^{n}\right|+1}$.

(b) The relative errors.

(d) Computational time.

Figure: (a) Numerical solutions for $\alpha=0.1,0.5,0.9$. (b) the errors between numerical solutions and reference solutions for different

Consider the following time-fractional Allen-Cahn equation

$$
\left\{\begin{align*}
{ }_{C} D_{0, t}^{\alpha} u(\mathbf{x}, t) & =\gamma\left(\varepsilon \Delta u(\mathbf{x}, t)-\varepsilon^{-1} F^{\prime}(u)\right), & & (\mathbf{x}, t) \in \Omega \times(0, T]  \tag{53}\\
u(\mathbf{x}, 0) & =u_{0}(\mathbf{x}), & & \mathbf{x} \in \Omega,
\end{align*}\right.
$$

subject to periodic boundary conditions, where $\alpha \in(0,1], \Omega \subset \mathbb{R}^{d}, \mathbf{x}=(x, y)$ for $d=2, \mathbf{x}=(x, y, z)$ for $d=3, \varepsilon$ is the thickness of phase interface, $\gamma$ is mobility constant, and $F$ is defined by

$$
F(u)=\frac{1}{4}\left(1-u^{2}\right)^{2}
$$

The computational domain $\Omega=(-1,1)^{2}$ is partitioned uniformly into $128 \times 128$ subdomains, $\varepsilon=0.02$, and $\gamma=0.02$. The initial condition is taken as

$$
\begin{aligned}
u_{0}= & -\tanh \left(\left((x-0.3)^{2}+y^{2}-0.2^{2}\right) / \varepsilon\right) \tanh \left(\left((x+0.3)^{2}+y^{2}-0.2^{2}\right) / \varepsilon\right) \\
& \times \tanh \left(\left(x^{2}+(y-0.3)^{2}-0.2^{2}\right) / \varepsilon\right) \tanh \left(\left(x^{2}+(y+0.3)^{2}-0.2^{2}\right) / \varepsilon\right) .
\end{aligned}
$$

Figure: Numerical solutions of the Allen-Cahn equation (53). Solution snapshots at $t=1,10,50,100$ (from top to bottom) for three fractional orders $\alpha=0.4,0.7,0.9$ (from left to right).

Figure: Numerical solutions of (53) with variable-order $\alpha(t)=0.4+\sin ^{2}(t) / 2$. Solution snapshots at $t=1,30,50$ (top: from left to right) and $t=100,150,200$ (bottom: from left to right).

(a) The active memory requirement.

(b) The computational time.

Figure: The comparison of the fast method (red stars) and direct method (blue circles) for solving two-dimensional Allen-Cahn equation (53) with the time step size $\tau=0.01$, the spatial step size $h=1 / 64$, and $\alpha=0.9$. We can see that the proposed unified fast method can significantly reduce the memory and thus use much less time than that of the direct method.

Three-dimensional time-fractional Allen-Cahn equation (53) subject to the following initial condition

$$
u_{0}=\tanh \left(\frac{1+0.2 \cos (6 \theta)-\sqrt{x^{2}+2 y^{2}+z^{2}}}{\sqrt{2} \varepsilon}\right)
$$

where $\theta=\tan ^{-1}(z / x)$. The computational domain $\Omega=(-1.5,1.5)^{3}$ is divided uniformly into $32 \times 32 \times 32$ subdomains, $\varepsilon=0.05$, and $\gamma=0.05$. The time step size is taken as $\tau=0.01$.
The initial condition is a star-shaped ball, which becomes smaller as the time $t$ increases for $\alpha=0.4,0.7,0.9$. For a fixed time $t$, the ball becomes smaller as the fractional order $\alpha$ becomes larger.

Figure: Numerical solutions of the three-dimensional Allen-Cahn equation (53). Solution snapshots at $t=1,10,50,100$ (from left to right) for three fractional orders $\alpha=0.4,0.7,0.9$ (from top to bottom).

Figure: Snapshots of numerical solutions of the three-dimensional Allen-Cahn equation (53). Top: $\alpha=0.4, t=300,500,800,1000$ (from left to right); center: $\alpha=0.7, t=140,200,250,300$ (from left to right); bottom: $\alpha=0.9, t=110,120,130,140$ (from left to right).

Consider the following one-dimensional Schrödinger equation

$$
\left\{\begin{align*}
\mathrm{i} u_{t}(x, t) & =-u_{x x}(x, t), & & \text { for } t>0, \quad x \in \mathbb{R}  \tag{54}\\
u(x, 0) & =u_{0}(x), & & \text { for } x \in \mathbb{R}
\end{align*}\right.
$$

In applications, we are concerned with the solution on the bounded domain $x \in \Omega$, for example, $\Omega=[-3,3]$. In such a case, (54) is equivalent to a time-dependent Schrödinger equation with nonreflecting boundary conditions [?]

$$
\begin{cases}\mathrm{i} u_{t}(t)=-u_{x x}(t), & \text { for } t>0  \tag{55}\\ u(x, t)=e^{\frac{\pi}{4} \mathrm{i}}\left(k_{1 / 2} * u_{x}\right)(t), & \text { at } x=-3 \\ u(x, t)=-e^{\frac{\pi}{4} \mathrm{i}}\left(k_{1 / 2} * u_{x}\right)(t), & \text { at } x=+3 \\ u(x, 0)=u_{0}(x), & \text { for } x \in[-3,3]\end{cases}
$$

where $\mathrm{i}^{2}=-1$ and $u(t)=u(x, t), u_{x}(t)=u_{x}(x, t)=\partial_{x} u(x, t)$.

The Crank-Nicolson method is applied to the first equation in (55), the fractional integral operator in the second or third equation in (55) is discretized by the fast Algorithm 1, we obtain a semi-discrete method for (55) as follows:
Find $U^{n}=U\left(\cdot, t_{n}\right)$ for $n \geq 1$ such that

$$
\begin{cases}i \frac{U^{n}-U^{n-1}}{t_{n}-t_{n-1}}=-\frac{U_{x x}^{n}+U_{x x}^{n-1}}{2}, & \text { for } x \in(-3,3),  \tag{56}\\ U^{n}( \pm 3)=\mp e^{\frac{\pi}{4} \mathrm{i}}{ }_{F} D^{-1 / 2, n} U_{x}( \pm 3), & \\ U^{0}(x)=u_{0}(x), & \text { for } x \in[-3,3]\end{cases}
$$

The initial data $u(x, 0)=\frac{1}{\sqrt{\xi}} e^{\mathrm{i} k x-x^{2} /(4 \xi)}$. The exact solution of (54) is

$$
u(x, t)=\frac{1}{\sqrt{\xi+\mathrm{i} t}} e^{\mathrm{i} k(x-k t)-(x-2 k t)^{2} / 4(\xi+\mathrm{i} t)}, \quad \xi, k \in \mathbb{R} .
$$

(a) Real part.

(c) Absolute values.

(b) Imaginary part.

(d) Point-wise errors.

Figure: Numerical solutions of the Schrödinger equation (54) on the interval $[-3,3], h=\tau=0.001, \xi=0.04, k=2$. (a) The real part of the numerical solution: (b) The imaginary nart of the numerical solution: (c)

(a) The $L^{2}$ error at $t=2$.

(b) The computational time.

Figure: (a) The $L^{2}$ errors of the numerical solution under different time step size; (b) Comparison of the computational time between the fast method and the direct method.
